

# SOIL SAMPLING

Soil sampling is a good start for any fertility program. Test results identify available nutrients in the soil, allowing you to address nutrient deficiencies and improve the nutritional profile of your fields. For example, you may have one area that requires more lime than another does. It does not make sense to put the same rate of product on both places, each with different needs. Proper nutrient management can help you budget in-field resources, optimizing your potential return on investment.
